## Applications of Differential Equations

Within mathematics, a differential equation refers to an equation that brings in association one or more functions and their derivatives. In applications, the functions usually denote the physical quantities whereas the derivatives denote their rates of alteration, and the differential equation represents a relationship between the two.

In mathematics, a differential equation is an equation that relates one or more functions and their derivatives. In applications, the functions generally represent physical quantities, the derivatives represent their rates of change, and the differential equation defines a relationship between the two. Such relations are common; therefore, differential equations play a prominent role in many disciplines including engineering, physics, economics, and biology. Mainly the study of differential equa

Like any other mathematical expression, differential equations (DE) are used to represent any phenomena in the world. One of which is growth and decay – a simple type of DE application yet is very useful in modelling exponential events like radioactive decay, and population growth.

## Growth and Decay: Applications of Differential Equations ...

Differential Equation applications have significance in both academic and real life. An equation denotes the relation between two quantity or two functions or two variables or set of variables or between two functions. Differential equation denotes the relationship between a function and its derivatives, with some set of formulas.

This differential equation has the general solution  $x(t) = c_1 \cos t + c_2 \sin t$ ,  $\text{\label{GeneralSol}}$  which gives the position of the mass at any point in time. The motion of the mass is called simple harmonic motion. The period of this motion (the time it takes to complete one oscillation) is  $(T = \frac{2\pi}{\omega})$  and the frequency is  $(f = \frac{1}{T} = \frac{\omega}{2\pi})$  (Figure  $\text{\PageIndex{2}}$ ).

In Science and Engineering problems, we always seek a solution of the differential equation which satisfies some specified conditions known as the boundary conditions. The differential equation together with the boundary conditions constitutes a boundary value problem.

## ~~Applications of Partial Differential Equations~~

Differential equations involve the differential of a quantity: how rapidly that quantity changes with respect to change in another. For instance, an ordinary differential equation in  $x(t)$  might involve  $x$ ,  $t$ ,  $dx/dt$ ,  $d^2x/dt^2$  and perhaps other derivatives. We'll look at two simple examples of ordinary differential equations below, solve them in ...

The differential equation is second order linear with constant coefficients, and its corresponding homogeneous equation is where  $B = K/m$ . The auxiliary polynomial equation,  $r^2 = Br = 0$ , has  $r = 0$  and  $r = -B$  as roots. Since these are real and distinct, the general solution of the corresponding homogeneous equation is

Differential equations are of two types for the purpose of this work, namely: Ordinary Differential Equations and Partial Differential Equations. Ordinary Differential Equations (ODEs) An ordinary differential equation is an equation that contains one or several derivatives of an unknown function, which we usually call  $y(x)$  (or sometimes  $y(t)$  if the independent variable is time  $t$ ).

Therefore, the differential equation describing the orthogonal trajectories is . since the right hand side of (\*\*\*) is the negative reciprocal of the right hand side of (\*). If equation (\*\*\*) is written in the form . note that it is not exact (since  $M_y = 2y$  but  $N_x = -2y$ ). However, because . is a function of  $x$  alone, the differential ...
